Electron-phonon interaction in a semiconductor is the main factor for relaxation of a transferred electron. There are two different relaxation processes that decrease the efficiency of light conversion in a solar system: (1) relaxation of an electron from a semiconductor conduction band to a valence band and (2) a backward electron transfer reaction.

14.4 Electron-phonon interactions. The electron-phonon interaction also contributes to the self-energy of an electron. This dependence is usually not an important aspect of photoemission in simple metals. However, the electron-phonon interaction is important for other systems.

Abstract. Scattering of the electrons, or the holes, from one state to another, whether this scattering occurs due to the lattice vibrations or by the Coulomb field of impurities or some other process, is one of the most important processes in the transport of the carriers through the semiconductor.

### Electron-phonon interactions from first principles

The electron-phonon interaction is presented in detail starting from its most general formulation, considering nonpolar (deformation potential) and polar (Fröhlich) interactions. The possible way to calculate the nonpolar electron-phonon matrix elements using DFT is discussed and the rigid-ion approximation is developed in detail.

It has long been recognized that the electron-phonon interactions dominate transport theory: the study of electrical and thermal resistivity [1, 6]. These interactions are responsible for all thermo-electric effects [1, 6, 11] and

We have set the oscillator mass  $M = 1$  and will also use units in which  $\hbar = k_B = 1$  and the hopping amplitude  $t = 1$ . ### Electron-Phonon Interactions in Flat Band Systems

Because of the quasielasticity of the electron-phonon (e-ph) interactions, the maximal phonon momentum in an e-ph scattering event is limited to  $2k_F$ , representing a full backscattering of the electrons across the Fermi surface of radius  $k_F$ . Since in metals  $k_F$  is of the size of the Brillouin Zone (BZ),  $2k_F > k_D$ , all populated phonons can

Electrons interact with these displacements, and this interaction is known as electron-phonon coupling. One of possible scenarios was proposed in the seminal 1933 paper by Lev Landau, which includes the production of a lattice defect such as an F-center and a trapping of the electron by this defect.

Abstract. We include the treatment of quadrupolar fields beyond the Fröhlich interaction in the first-principles electron-phonon vertex in semiconductors. Such quadrupolar fields induce long-range interactions that have to be taken into account for accurate physical results. We apply our formalism to Si (nonpolar), GaAs, and GaP (polar) and demonstrate that electron mobilities show large errors if dynamical quadrupoles are not properly treated.
