The book covers the two basic methods of approaching Algebraic Number Theory, using ideals and valuations, and includes material on the most usual kinds of algebraic number field, the functional equation of the zeta function and a substantial digression on the classical approach to Fermat's Last Theorem, as well as a comprehensive account of class field theory.

This account of Algebraic Number Theory is written primarily for beginning graduate students in pure mathematics, and encompasses everything that most such students are likely to need; others who need the material will also find it accessible. It assumes no prior knowledge of the subject, but a firm basis in the theory of field extensions at an undergraduate level is required, and an appendix ...

A division algebra with commutative multiplication. Division algebra (A, +,?,0, 1, ??) Laws: (A, +,?,0, 1) is commutative; Lattice-like Structures. There are some cool things about lattices that aren't covered here, but lattice-like structures will be getting their very own followup post at some point in the (hopefully near) future.

A Guide to Algebraic Expressions Teaching Approach In this series, we revise the basics of algebra such as number systems and products, we then establish the concepts of factorisation and algebraic fractions. The series covers a brief revision of number systems. In addition we revise the distributive law and FOIL and teach

Algebraic geometry is fairly easy to describe from the classical viewpoint: it is the study of algebraic sets (de?ned in x^2) and regular mappings between such sets. (Regular mappings are also de?ned in x^2 .)

A number ?eld K is a ?nite algebraic extension of the rational numbers Q . Every such extension can be represented as all polynomials in an algebraic number α : $K = Q(\alpha) = \{X^n + a_{n-1}X^{n-1} + \dots + a_0 \mid a_i \in Q\}$. Here α is a root of a polynomial with coefficients in Q . Algebraic number theory involves using techniques from (mostly commutative)

Swinnerton-Dyer's A brief guide to algebraic number theory has a different definition of norm of an ideal (page 25). Namely if A is an ideal of OL , it is defined as $N(A) = \text{ideal in } OK \text{ generated by elements } N(a) \text{ where } a \in A$. I don't know why these two definitions are the same. Swinnerton-Dyer claims so in his book.

Definition. Let $L=K[x]$ be an extension and let L be algebraic over K . We define the degree of L over K to be the degree of its minimal polynomial $f(x) \in K[X]$. Example 4. x^2 has degree 2 over Q but degree 1 over R . By Example 3, $x^2 + i$ has degree 4 over Q , degree 2 over $Q(p^2)$ and degree 1 over $Q(p^2;i)$. Definition. L is called an algebraic number if L is algebraic over Q .
